Received 26 October 2016

A variety of logical frameworks support the use of higher-order abstract syntax in representing formal systems. Although these systems seem superficially the same, they differ in a variety of ways; for example, how they handle a context of assumptions and which theorems about a given formal system can be concisely expressed and proved. Our contributions in this paper are two-fold: 1) we develop a common infrastructure and language for describing benchmarks for systems supporting reasoning with binders, and 2) we present several concrete benchmarks, which highlight a variety of different aspects of reasoning within a context of assumptions. Our work provides the background for the qualitative comparison of different systems that we have completed in a separate paper. It also allows us to outline future fundamental research questions regarding the design and implementation of meta-reasoning systems.

1. Introduction

Ten years ago the PoplMark challenge [Aydemir et al., 2005] stimulated considerable interest in mechanizing the meta-theory of programming languages and it has played a substantial role in the wide-spread use of proof assistants to prove properties, for example, of parts of a compiler or of a language design. The PoplMark challenge concentrated on summarizing the state of the art, identifying best practices for (programming language) researchers embarking on formalizing language definitions, and identifying a list of engineering improvements to make the use of proof assistants (more) common place. While these are important questions whose answers will foster the adoption of proof assistants by non-experts, it neglects some of the deeper fundamental questions: What should existing or future meta-languages and meta-reasoning environments look like and what requirements should they satisfy? What support should an ideal meta-language and proof environment give to facilitate mechanizing meta-reasoning? How can its design reflect and support these ideals?

We believe “good” meta-languages should free the user from dealing with tedious bureaucratic details, so s/he is able to concentrate on the essence of a proof or algorithm.
Ultimately, this means that users will mechanize proofs more quickly. In addition, since
effort is not wasted on cumbersome details, proofs are more likely to capture only the
essential steps of the reasoning process, and as a result, may be easier to trust. For
instance, weakening is a typical low-level lemma that is used pervasively (and sometimes
silently) in a proof. Freeing the user of such details ultimately may also mean that the
automation of such proofs is more feasible.

One fundamental question when mechanizing formal systems and their meta-theory
is how to represent variables and variable binding structures. There is a wide range of
answers to this question from using de Bruijn indices to locally nameless representations,
and nominal encodings, etc. For a partial view of the field see the papers collected in
the Journal of Automated Reasoning’s special issue dedicated to POPLMARK [Pierce and
Weirich, 2012] and the one on “Abstraction, Substitution and Naming” [Fernández and
Urban, 2012].

Encoding object languages and logics (OLs) via higher-order abstract syntax (HOAS),
sometimes referred to as “lambda-tree syntax” [Miller and Palamidessi, 1999], where we
utilize meta-level binders to model object-level binders is in our opinion the most ad-
vanced technology. HOAS avoids implementing common yet notoriously tricky routines
dealing with variables, such as capture-avoiding substitution, renaming, and fresh name
generation. Compared to other techniques, HOAS leads to very concise and elegant en-
codings and provides significant support for such an endeavor. Concentrating on encoding
binders, however, neglects another important and fundamental aspect: the support for
hypothetical and parametric reasoning, in other words reasoning within a context of as-
sumptions. Considering a derivation within a context is common place in programming
language theory and leads to several natural questions: How do we model the context of
assumptions? How do we know that a derivation is sensible within the scope of a con-
text? Can we model the relationships between different contexts? How do we deal with
structural properties of contexts such as weakening, strengthening, and exchange? How
do we know assumptions in a context occur uniquely? How do we take advantage of the
HOAS approach to substitution?

Even in systems supporting HOAS there is not a uniform answer to these questions.
On one side of the spectrum we have systems that implement various dependently-
typed calculi. Such systems include the logical framework Twelf [Schürmann, 2009],
the dependently-typed functional language Beluga [Pientka, 2008, Pientka and Dunfield,
2010, Pientka and Cave, 2015], and Delphin [Poswolsky and Schürmann, 2008]. All these
systems also provide, to various degrees, built-in support for reasoning modulo structural
properties of a context of assumptions.

On the other side there are systems based on a proof-theoretic foundation, which
follow a two-level approach: they implement a specification logic (SL) inside a higher-
order logic or type theory. Hypothetical judgments of object languages are modeled using
implication in the SL and parametric judgments are handled via (generic) universal
quantification. Contexts are commonly represented explicitly as lists or sets in the SL,
and structural properties are established separately as lemmas. For example substituting
for an assumption is justified by appealing to the cut-admissibility lemma of the SL.
These lemmas are not directly and intrinsically supported through the SL, but may be
integrated into a system’s automated proving procedures, usually via tactics. Systems following this philosophy are for instance the two-level Hybrid system [Momigliano et al., 2008, Felty and Momigliano, 2012] as implemented on top of Coq and Isabelle/HOL, and the Abella system [Gacek, 2008].

The contributions of the present paper are as follows: we develop a common framework and infrastructure for representing and describing benchmarks for systems supporting reasoning with binders; in particular, we develop notation to view contexts as “structured sequences” and classify contexts using schemas. Moreover, we abstractly characterize in a uniform way basic structural properties that many object languages satisfy, such as weakening, strengthening, and exchange. This lays the foundation for describing benchmarks and comparing different approaches to mechanizing OLs. Second, we propose several challenge problems that are crafted to highlight the differences between the designs of various meta-languages with respect to reasoning with and within a context of assumptions, in view of their mechanization in a given proof assistant. Using our common framework and language, we develop the proofs for these challenge problems in a systematic way. This provides a general footprint for mechanizing these examples, as we will see later.

In a related paper [Felty et al., 2015a], we have carried out such a mechanization and comparison in four systems: Twelf, Beluga, Hybrid, and Abella. The common framework we present here was key for the systematic comparison of these systems and understanding the trade-offs between them. It also may be seen as a first step towards developing a formal translation between different foundations, e.g., a translation between Beluga’s type-theoretic foundation and the proof-theory underlying systems such as Hybrid or Abella.

We have also started an open repository of benchmarks called ORBI (Open challenge problem Repository for systems supporting reasoning with Binders), described in [Felty et al., 2015b]. ORBI includes a language for presenting benchmarks based on the common framework that we develop in this paper.

Challenge problems are important as they serve as an excellent regression suite and provide the basis for highlighting differences between and strengths and limitations of various systems. The problems described here can be viewed as an initial set. We hope that others will contribute to the benchmark repository, implement these challenge problems, and further our understanding of the trade-offs involved in choosing one system over another for this kind of reasoning. A solution to the proposed benchmarks should include an adequate way to represent syntax, contexts and judgment and a mechanized proof of those theorems.

The paper is structured as follows: In Sect. 2 we motivate our definition of contexts as “structured sequences,” which refines the standard view of contexts, and we describe generically and abstractly some context properties. Using this terminology we then present the benchmarks and their proofs in Sect. 3. We conclude in Sect. 4 discussing related and future work. Appendix A provides a quick reference guide to the benchmarks. Full details about the challenge problems and their mechanization can be found at https://github.com/pientka/ORBI. The notation as well as the mechanization of these benchmarks in the four systems mentioned above are described in separate papers, [Felty et al., 2015b] and [Felty et al., 2015a], respectively.
2. Contexts of Assumptions: Preliminaries and Terminology

Our description follows mathematical practice, in contrast to giving a fully formal account based on, for example, type theory. In fact, all the notions that we touch upon in this section, such as substitution, \(\alpha\)-renaming, bindings, context schemas to name a few, can and have been generally treated in Beluga, see e.g., [Pientka, 2008]. However, we deliberately choose not to force upon us one particular foundation, so as to make our benchmarks more accessible to a wider audience.

2.1. Defining Well-formed Objects

The first question that we face when defining an OL is how to describe well-formed objects. Consider the polymorphic lambda-calculus. Commonly the grammar of this language is defined using Backus-Naur form (BNF) as follows.

\[
\begin{align*}
\text{Types} & \quad A, B ::= \alpha | arr AB | all \alpha. A \\
\text{Terms} & \quad M ::= x | \text{lam} x. M | \text{app} M_1 M_2 | \text{tlam} \alpha. M | \text{tapp} M A
\end{align*}
\]

The grammar, however, does not capture properties of interest such as when a given term or type is \textit{closed}. Alternatively, we can describe well-formed types and terms as \textit{judgments} using axioms and inference rules following [Martin-Löf, 1996], as popularized in programming language theory by Pfenning’s \textit{Computation and Deduction} notes [Pfenning, 2001].

We start with an \textit{implicit-context} version of the rules for well-formed types and terms that plays the part of the above BNF grammar, but is also significantly more expressive. To describe whether a type \(A\) or term \(M\) is well-formed we use two judgments: \(\text{is\_tp} A\) and \(\text{is\_tm} M\), whose formation rules are as follows:

- **Type \(A\) is well-formed**
  \[
  \frac{\text{is\_tp } \alpha \quad \text{tp}_v}{\text{is\_tp } \alpha \quad \text{tp}_v} \hspace{1cm} \frac{\text{is\_tp } \alpha}{\text{is\_tp } \alpha} \hspace{1cm} \frac{\text{is\_tp } (\text{arr } AB) \quad \text{tp}_{ar}}{\text{is\_tp } (\text{all } \alpha. A) \quad \text{tp}_{all}}
  \]

- **Term \(M\) is well-formed**
  \[
  \frac{\text{is\_tm } x \quad \text{tm}_v}{\text{is\_tm } x \quad \text{tm}_v} \hspace{1cm} \frac{\text{is\_tm } \alpha}{\text{is\_tm } \alpha} \hspace{1cm} \frac{\text{is\_tm } (\text{tlam } \alpha. M) \quad \text{tm}_{tl}}{\text{is\_tm } (\text{tapp } M A) \quad \text{tm}_{ta}}
  \]

The rule for function types \((\text{tp}_{ar})\) is unsurprising. The rule \(\text{tp}_{all}\) states that a type
all $\alpha. A$ is well-formed if $A$ is well-formed under the assumption that the variable $\alpha$ is also. We say that this rule is *parametric* in the name of the bound variable $\alpha$—thus implicitly enforcing the usual eigenvariable condition, since bound variables can be $\alpha$-renamed at will—and *hypothetical* in the name of the axiom $(tp)$ stating the well-formedness of this type variable. In this two-dimensional representation, derived from Gentzen’s presentation of natural deduction, we do not have an explicit rule for variables; instead, for each type variable introduced by $tp_{\alpha}$ we also introduce the well-formedness assumption about that variable, and we explicitly include names for the bound variable and axiom as parameters to the rule name.

While variables might occur free in a type given via the BNF grammar, the two-dimensional implicit-context formulation models more cleanly the *scope* of variables; e.g., a type $is_{tp} (all \alpha. arr \alpha \beta)$ is only meaningful in the context where we have the assumption $is_{tp} \beta$.

Following this judgmental view, we can also characterize well-formed terms; the rule for term application $(tm_a)$ is straightforward and the rule for type application $(tm_a)$ simply refers to the previous judgment for well-formed types since types are embedded in terms. The rules for term abstraction $(tm_{\alpha})$ and type abstraction $(tm_{\alpha})$ are again the most interesting. The rule $tm_{\alpha}$ is parametric in the variable $x$ and hypothetical in the assumption $is_{tm} x$; similarly the rule $tm_{\alpha}$ is parametric in the type variable $\alpha$ and hypothetical in the assumption $is_{tp} \alpha$.

We emphasize that mechanizations of a given object language can use either one of these two representations, the BNF grammar or the judgmental implicit context formulation. However, it is important to understand how to move between these representations and the trade-offs and consequences involved. For example, if we choose to support the BNF-style representation of object languages in a proof assistant, we might need to provide basic predicates that verify whether a given object is closed; further we may need to reason explicitly about the scope of variables. HOAS-style proof assistants typically adopt the judgmental view providing a uniform treatment for objects themselves (well-formedness rules) and other inference rules about them.

2.2. Context Definitions

Introducing the appropriate assumption about each variable is a general methodology that scales to OLs accommodating much more expressive assumptions. For example, when we specify typing rules, we introduce a typing assumption that keeps track of the fact that a given variable has a certain type. This approach can also result in compact and elegant proofs. Yet, it is often convenient to present hypothetical judgments in a *localized* form, reducing some of the ambiguity of the two-dimensional notation. We therefore introduce an *explicit* context for bookkeeping, since when establishing properties about a given system, it allows us to consider the variable case(s) separately and to state clearly when considering closed objects, i.e., an object in the empty context. More importantly, while structural properties of contexts are implicitly present in the above presentation of inference rules (where assumptions are managed informally), the explicit
context presentation makes them more apparent and highlights their use in reasoning about contexts.

To contrast the representation using explicit contexts to implicit ones and to highlight the differences, we re-formulate the earlier rules for well-formed types and terms given on page 4 using explicit contexts in Sect. 2.4. As another example of using explicit contexts, we give the standard typing rules for the polymorphic lambda-calculus (see Sect. 2.4). The reader might want to skip ahead to get an intuition of what explicit contexts are and how they are used in practice. In the rest of this section, we first introduce terminology for structuring such contexts, and then describe structural properties they (might) satisfy.

Traditionally, a context of assumptions is characterized as a sequence of formulas $A_1, A_2, \ldots, A_n$ listing its elements separated by commas [Pierce, 2002, Girard et al., 1990]. However, we argue that this is not expressive enough to capture the structure present in contexts, especially when mechanizing OLs. In fact, there are two limitations from that point of view.

First, simply stating that a context is a sequence of formulas does not characterize adequately and precisely what assumptions can occur in a context and in what order. For example, to characterize a well-formed type, we consider a type in a context $\Phi_\alpha$ of type variables. To characterize a well-formed term, we must consider the term in a context $\Phi_\alpha x$ that may contain type variables $\alpha$ and term variables $x$.

As a consequence, we need to be able to state in our mechanization when a given context satisfies being a well-formed context $\Phi_\alpha$ or $\Phi_\alpha x$. In other words, the grammar for $\Phi_\alpha$ and $\Phi_\alpha x$ will give rise to a schema, which describes when a context is meaningful. Simply stating that a context is a sequence of assumptions does not allow us necessarily to distinguish between different contexts.

Second, forming new contexts by a comma does not capture enough structure. For example, consider the typing rule for lambda-abstraction that states that $(\text{lam } x. M)$ has type $(\text{arr } C B)$, if assuming that $x$ is a term variable and $x$ has type $C$, we can show that $M$ has type $B$. Note that whenever we introduce assumptions $x:C$ (read as “term variable $x$ has type $C$”), we at the same time introduce the additional assumption that $x$ is a new term variable. This is indeed important, since from it we can derive the fact that every typing assumption is unique. Simply stating that the typing context is a list of assumptions $x:C$, as shown below in the first attempt, fails to capture that $x$ is a term variable, distinct from all other term variables. In fact, it says nothing about $x$.

Typing context (attempt 1) $\Phi ::= \cdot \mid \Phi, x:C$

The second attempt below also fails, because the occurrences of the comma have two different meanings.

Typing context (attempt 2) $\Phi ::= \cdot \mid \Phi, \text{is_tm } x, x:C$

The comma between $\text{is_tm } x, x:C$ indicates that whenever we have an assumption $\text{is_tm } x$, we also have an assumption $x:C$. These assumptions come in pairs and form one block of
assumptions. On the other hand, the comma between $\Phi$ and $is\_tm\ x, x:C$ indicates that the context $\Phi$ is extended by the block containing assumptions $is\_tm\ x$ and $x:C$.

Taking into account such blocks leads to the definition of contexts as structured sequences. A context is a sequence of declarations $D$ where a declaration is a block of individual atomic assumptions separated by ‘;’. The ‘;’ binds tighter than ‘,’. We treat contexts as ordered, i.e., later assumptions in the context may depend on earlier ones, but not vice versa—this is in contrast to viewing contexts as multi-sets.

We thus introduce the following categories:

- **Atom** $A$
- **Block of declarations** $D ::= A \mid D; A$
- **Context** $\Gamma ::= \cdot \mid \Gamma, D$
- **Schema** $S ::= D_s \mid D_s + S$

Just as types classify terms, a schema will classify meaningful structured sequences. A schema consists of declarations $D_s$, where we use the subscript $s$ to indicate that the declaration occurring in a concrete context having schema $S$ may be an instance of $D_s$. We use $+$ to denote the alternatives in a context schema.

We can declare the schemas corresponding to the previous contexts, seen as structured sequences, as follows:

- $S_\alpha ::= is\_tp\ \alpha$
- $S_{\alpha x} ::= is\_tp\ \alpha + is\_tm\ x$
- $S_{\alpha t} ::= is\_tp\ \alpha + is\_tm\ x; x:C$

We use the following notational convention for declarations and schemas: Lower case letters denote bound variables (eigenvariables), obeying the Barendregt variable convention; $EV(D)$ will denote the set of eigenvariables occurring in $D$. Upper case letters are used for “schematic” variables. Therefore, we can always rename the $x$ in the declaration $is\_tm\ x; x:C$ and instantiate $C$. For example, the context

$$is\_tm\ y; y: nat, is\_tp\ \alpha, is\_tm\ z; z: (arr\ \alpha\ \alpha)$$

fits the schema $S_{\alpha t}$. Although a schema does not appear to have an explicit binder, all the eigenvariables and schematic variables occurring are considered bound. Beluga’s type theory provides a formal type-theoretic foundation for describing schemas where the scope of eigenvariables and schematic variables in a schema is enforced using $\Sigma$ and $\Pi$-types [Pientka and Dunfield, 2008, Cave and Pientka, 2012].

We say that a declaration $D$ is well-formed if for every $x \in EV(D)$ there is an atom in $D$ (notation $A \in D$) denoting the well-formedness judgment for $x$, which we generically refer to as $is\_wf\ x$, with the proviso that $is\_wf\ x$ precedes its use in $D$; the meta-notation $is\_wf$ will be instantiated by an appropriate atom such as $is\_tm$ or $is\_tp$. A schema is well-formed if and only if all its declarations are well-formed. For example, the schema $S_{\alpha t}$ is well-formed since the $x$ in $x:C$ is declared by $is\_tm\ x$ appearing earlier in the same declaration. We will assume in the following that all schemas are such.

More generally, we say that a concrete context $\Gamma$ has schema $S$ ($\Gamma:has\_schema\ S$), if every declaration in $\Gamma$ is an instance of some declaration $D_s$ in $S$. By convention,
when we write $S_l$ to denote a context schema, $\Gamma_l$ will denote a valid instance of $S_l$, namely such that $\Gamma_l$ has schema $S_l$, where subscript $l$ is used to denote the relationship between the schema and an instance of it.

\[
\text{Schema Satisfaction} \quad \Gamma \text{ has schema } S \\
\quad \Gamma \text{ has schema } S \\
\quad D \in S \\
\quad \text{EV}(D) \cap \text{EV}(\Gamma) = \emptyset \\
\quad (\Gamma, D) \text{ has schema } S
\]

Block $D$ of Declaration is valid $D \in S$

$D$ instance of $D_s$ $D \in D_s$ $D \in D_s$ + $S$

$D$ instance of $D_s$ $D \in D_s$ $D \in D_s$ + $S$

Note that if $D \in S$, then it is by definition well-formed. The premise $\text{EV}(D) \cap \text{EV}(\Gamma) = \emptyset$ requires eigenvariables in different blocks in a context satisfying the schema to be distinct from each other. This constraint will always be satisfied by contexts that appear in proofs of judgments using our inference rules—again, see for example the inference rules in Sect. 2.4. We remark that a given context can in principle inhabit different schemas; for example the context $\text{is}\_\text{tp} \alpha_1, \text{is}\_\text{tp} \alpha_2$ has schema $S_\alpha$ but also inhabits schemas $S_{\alpha x}$ and $S_{\alpha t}$.

Note that according to the given grammar for schemas, contexts contain only atomic assumptions. We could consider non-atomic assumptions; in fact, more complex assumptions are not only possible, but sometimes yield very compact and elegant specifications, as we touch upon in Sect. 4. However, to account for them, we would need to introduce a language for terms and formulas that we feel would detract from the goal at hand.

2.3. Structural Properties of Contexts

So far we have introduced terminology for describing objects in three different ways: using a BNF grammar, defining objects and rules via a two-dimensional implicit context, and using an explicit context containing structured sequences of assumptions following a given context schema. For the latter, we have not yet described the associated inference rules. Before we do (in Sect. 2.4 as mentioned), we introduce structural properties of explicit contexts generically and abstractly.

We concentrate here on developing a common framework for describing object languages including structural properties they might satisfy. However, we emphasize that whether a given object language does admit structural properties such as weakening or exchange is a property that needs to be verified on a case-by-case basis.\(^1\) In the subsequent discussion and in all our benchmarks, we concentrate on examples satisfying weakening, exchange, and strengthening, i.e., assumptions can be used as often as needed, they can be used in any order, and certain assumptions will be known not to be needed.

\[^1\] Existing metalanguages make similar commitments to structural properties: for example the LF type theory satisfies by construction those properties and so does a specification logic based on hereditarily Harrop formulae, as we elaborate in the companion paper [Felty et al., 2015a]
Our refined notion of context has an impact on structural properties of contexts: e.g., weakening can be described by adding a new declaration to a context, as well as adding an element inside a block of declarations. We distinguish between structural properties of a concrete context and structural properties of all contexts of a given schema. For example, given the context schemas $S_\alpha$ and $S_{\alpha x}$, we know that all concrete contexts of schema $S_{\alpha x}$ can be strengthened to obtain a concrete context of schema $S_\alpha$. Dually, we can think of weakening a context of schema $S_\alpha$ to a context of schema $S_{\alpha x}$. We introduce the operations $\text{rm}$ and $\text{perm}$, where $\text{rm}$ removes an element of a declaration, and $\text{perm}$ permutes the elements within a declaration.

**Definition 1 (Operations on Declarations).**

— Let $\text{rm}_A : S \to S'$ be a total function taking a (well-formed) declaration $D \in S$ and returning a (well formed) declaration $D' \in S'$ where $D'$ is $D$ with $A$ removed, if $A \in D$; otherwise $D' = D$. 

— Let $\text{perm}_\pi : S \to S'$ be a total function that permutes the elements of a (well-formed) declaration $D \in S$ according to $\pi$ to obtain a (well formed) declaration $D' \in S'$.

Using these operations on declarations we state structural properties of declarations, later to be extended to contexts. These make no assumptions and give no guarantees about the schema of the context $\Gamma, D$ and the resulting context $\Gamma, f(D)$ where $f \in \{\text{rm}_A, \text{perm}_\pi\}$. In fact, we often want to use these properties when $\Gamma$ satisfies some schema $S$, but $D$ does not yet fit $S$; in this case, we apply an operation to $D$ so that $\Gamma, f(D)$ does satisfy the schema $S$.

Since our context schema may contain alternatives, the function $\text{rm}$ is defined via case-analysis covering all the possibilities, where we describe dropping all assumptions of a case using a dot, e.g., $\text{is}_\text{tm} x \mapsto \cdot$. For example:

— $\text{rm}_x : S_{\alpha t} \to S_{\alpha x} = \lambda d. \text{case } d \text{ of } \text{is}_\text{tp} \alpha \mapsto \text{is}_\text{tp} \alpha | \text{is}_\text{tm} y; y : A \mapsto \text{is}_\text{tm} y$

— $\text{rm}_\text{is}_\text{tm} x : S_{\alpha x} \to S_\alpha = \lambda d. \text{case } d \text{ of } \text{is}_\text{tp} \alpha \mapsto \text{is}_\text{tp} \alpha | \text{is}_\text{tm} y \mapsto \cdot$

**Property 2 (Structural Properties of Declarations).**

1 Declaration Weakening:

$$
\frac{\Gamma, \text{rm}_A(D), \Gamma' \vdash J}{\Gamma, D, \Gamma' \vdash J} \quad \text{d-wk}
$$

2 Declaration Strengthening:

$$
\frac{\Gamma, D, \Gamma' \vdash J}{\Gamma, \text{rm}_A(D), \Gamma' \vdash J} \quad \text{d-str}\dagger
$$

with the proviso ($\dagger$) that $A$ is irrelevant to $J$ and $\Gamma'$. In practice, this may be done by maintaining a dependency call graph of all judgments.

3 Declaration Exchange:

$$
\frac{\Gamma, D, \Gamma' \vdash J}{\Gamma, \text{perm}_\pi(D), \Gamma' \vdash J} \quad \text{d-exc}
$$
The special case $\text{rm}_A(A)$ drops $A$ completely, since
\[
\text{rm}_A = \lambda d. \text{case } d \text{ of } A \to \cdot | \ldots
\]
We treat $\Gamma, \cdot, \Gamma'$ as equivalent to $\Gamma, \Gamma'$. Hence, in the special case where we have $\Gamma, \text{rm}_A(A), \Gamma'$, we obtain the well-known weakening and strengthening laws on contexts that are often stated as:
\[
\frac{\Gamma, A, \Gamma' \vdash J}{\Gamma, \Gamma' \vdash J} \text{str}^\dagger \quad \frac{\Gamma, \Gamma' \vdash J}{\Gamma, A, \Gamma' \vdash J} \text{wk}
\]
In contrast to the above, the general exchange property on blocks of declarations cannot be obtained “for free” from the above operations and we define it explicitly:

**Property 3 (Exchange).

\[
\frac{\Gamma, D', D, \Gamma' \vdash J}{\Gamma, D, D', \Gamma' \vdash J} \text{exc}
\]

with the proviso that the sub-context $D, D'$ is well-formed.

Further, we state structural properties of contexts generically. To “strengthen” all declarations in a given context $\Gamma$, we simply write $\text{rm}_A^\ast(\Gamma)$ using the $\ast$ superscript. More generally, by $f^\ast$ with $f \in \{\text{rm}_A, \text{perm}_\pi\}$, we mean the iteration of the operation $f$ over a context.

**Property 4 (Structural Properties of Contexts).

1. Context weakening

\[
\frac{\text{rm}_A^\ast(\Gamma) \vdash J}{\Gamma \vdash J} \text{c-wk}
\]

2. Context strengthening

\[
\frac{\Gamma \vdash J}{\text{rm}_A^\ast(\Gamma) \vdash J} \text{c-str}^\dagger
\]

with the proviso ($\dagger$) that declarations that are instances of $A$ are irrelevant to $J$.

3. Context exchange

\[
\frac{\Gamma \vdash J}{\text{perm}_\pi^\ast(\Gamma) \vdash J} \text{c-exc}
\]

Finally, by $\text{rm}_D$ (resp. $\text{rm}_D^\ast$), we mean the iteration of $\text{rm}_A$ (resp. $\text{rm}_A^\ast$) for every $A \in D$, while keeping the resulting declaration and the overall context well-formed, e.g.,
\[
\text{rm}_{\text{is}\_\text{tm} \; y \; : \; A}(\cdot) = \text{rm}_{\text{is}\_\text{tm} \; y}(\text{rm}_{y \; : \; A}(\cdot)).
\]
All the above properties are admissible with respect to those extended rm functions.

The following examples illustrate some of the subtleties of this machinery:

— $\Gamma, \text{rm}_x.A(\text{is}\_\text{tm} \; y; y: A) = \Gamma, \text{is}\_\text{tm} \; y$. Bound variables in the annotation of rm can always be renamed so that they are consistent with the eigenvariables used in the declaration.

— $\text{rm}_{\text{is}\_\text{tm} \; x_1, \text{is}\_\text{tp} \; \alpha, \text{is}\_\text{tp} \; \beta, \text{is}\_\text{tm} \; x_2} = \text{is}\_\text{tp} \; \alpha, \text{is}\_\text{tp} \; \beta$. Here, the rm operation drops one of the alternatives in the schema $S_{x_2}$. 
Benchmarks for Bindings

11

— \( \text{rm}_{y:A}^\ast (\text{is\_tm}\ x_1; x_1:\text{nat}, \text{is\_tm}\ x_2; x_2:\text{bool}, \text{is\_tp}\ \alpha) = (\text{is\_tm}\ x_1, \text{is\_tm}\ x_2, \text{is\_tp}\ \alpha) \). The schematic variable \( A \) occurring in the annotation of \( \text{rm} \) will be instantiated with \( \text{nat} \) when strengthening the block \( \text{is\_tm}\ x_1; x_1:\text{nat} \) and similarly with \( \text{bool} \).

— \( \text{rm}_{y:A}^\ast (\text{is\_tp}\ \alpha, \text{is\_tp}\ \beta) = (\text{is\_tp}\ \alpha, \text{is\_tp}\ \beta) \). An \( \text{rm} \) operation may leave a context unchanged.

We state next the substitution properties for assumptions. The \textit{parametric substitution} property allows us to instantiate parameters, i.e., eigenvariables, in the context. For example, given \( \text{is\_tp}\ \alpha, \text{is\_tp}\ \beta \vdash J \) and a type \( \text{bool} \), we can obtain \( \text{is\_tp}\ \text{bool}, \text{is\_tp}\ \beta \vdash [\text{bool}/\alpha]J \) by replacing \( \alpha \) with \( \text{bool} \). The \textit{hypothetical substitution} property allows us to eliminate an atomic formula \( A \) that is part of a declaration \( D \). For example, given \( \text{is\_tp}\ \text{bool}, \text{is\_tp}\ \beta \vdash J \) and evidence that \( \text{is\_tp}\ \text{bool} \), we can obtain \( \text{is\_tp}\ \beta \vdash J \). In type theory the two substitution properties collapse into one.

Property 5 (Substitution Properties).

— \textbf{Hypothetical Substitution:}

If \( \Gamma_1, (D_1; A); D_2, \Gamma_2 \vdash J \) and \( \Gamma_1, D_1 \vdash A \), then \( \Gamma_1, (D_1; D_2), \Gamma_2 \vdash J \) provided that \( D_1; D_2 \) is a well-formed declaration in \( \Gamma_1 \).

— \textbf{Parametric Substitution:}

If \( \Gamma_1, (D_1; \text{is\_wf}\ x; D_2), \Gamma_2 \vdash J \), then \( \Gamma_1, (D_1; [t/x]D_2), [t/x]\Gamma_2 \vdash [t/x]J \) for any term \( t \) for which \( \Gamma_1, D_1 \vdash \text{is\_wf}\ t \) holds.

While parametric and hypothetical substitution do not preserve schema satisfaction by definition, we typically use them in such a way that contexts continue to satisfy a given schema.

We close this section recalling that, although we concentrate in our benchmarks on describing object languages that satisfy structural properties usually associated with intuitionistic logic, we note that our terminology can be used to also characterize substructural object languages. In the case of a linear object language, we might choose to only use operations such as \( \text{perm} \) and omit operations such as \( \text{rm} \) so as to faithfully and adequately characterize the allowed context operations.

2.4. The Polymorphic Lambda-Calculus Revisited

In systems supporting HOAS, inference rules are usually expressed using an implicit-context representation as illustrated on page 4. The need for explicit structured contexts, as discussed in Sects. 2.2 and 2.3, arises when performing meta-reasoning about the judgments expressed by these inference rules. In order to make the link, we revisit the example from Sect. 2.1 giving a presentation with explicit contexts, and then we make some preliminary remarks about context schemas and meta-reasoning. We will adopt the explicit-context representation of inference rules in the rest of the paper with the informal understanding of how to move between the implicit and explicit formulations.

In this formulation, depicted in Fig. 2.4 and differently from the implicit one, we have a base case for variables. Here, to look up an assumption in a context, we simply write \( A \in \Gamma \), meaning that there is some block \( D \) in context \( \Gamma \) such that \( A \in D \). For example
Well-formed Types

\[
\begin{align*}
\text{is\_tp} & \in \Gamma \\
\Gamma \vdash \text{is\_tp} \alpha & \quad \Gamma \vdash \text{is\_tp} B & \quad \Gamma, \text{is\_tp} \alpha \vdash \text{is\_tp} A & \quad \Gamma \vdash \text{is\_tp} (\text{all} \alpha. A) \\
\end{align*}
\]

Well-formed Terms

\[
\begin{align*}
is\_tm \; x & \in \Gamma \\
\Gamma \vdash \text{is\_tm} \; x & \quad \Gamma \vdash \text{is\_tm} (\text{lam} \; x. \; M) & \quad \Gamma, \text{is\_tp} \alpha \vdash \text{is\_tm} M & \quad \Gamma \vdash \text{is\_tm} (\text{tlam} \; \alpha. \; M) \\
\Gamma \vdash \text{is\_tm} \; M_1 & \quad \Gamma \vdash \text{is\_tm} \; M_2 & \quad \Gamma \vdash \text{is\_tp} A & \quad \Gamma \vdash \text{is\_tm} (\text{app} \; M_1 \; M_2) \\
\Gamma \vdash \text{is\_tm} (\text{lam} \; x. \; M) & \quad \Gamma \vdash \text{is\_tm} (\text{tlam} \; \alpha. \; M) & \quad \Gamma \vdash \text{is\_tm} (\text{tapp} \; M \; A) \\
\end{align*}
\]

Typing for the Polymorphic λ-Calculus

\[
\begin{align*}
x: B & \in \Gamma \\
\Gamma \vdash x : B & \quad \Gamma, \text{is\_tp} \alpha \vdash M : B & \quad \Gamma \vdash M : \text{all} \alpha. A & \quad \Gamma \vdash \text{is\_tp} B \\
\Gamma \vdash \text{is\_tm} (\text{app} \; M_1 \; M_2) & \quad \Gamma \vdash \text{is\_tm} (\text{tlam} \; \alpha. \; M) & \quad \Gamma \vdash \text{is\_tm} (\text{tapp} \; M \; A) \\
\end{align*}
\]

Fig. 1. Explicit-context Formulation of Inference Rules

\[
x: B \in \Gamma \text{ if } \Gamma \text{ contains block } \text{is\_tm} \; x : B. \text{ We will also overload the notation and write } D \in \Gamma \text{ to indicate that } \Gamma \text{ contains the entire block } D. \text{ We recall the distinction between the comma used to separate blocks, and the semi-colon used to separate atoms within blocks, as seen in the of}_I \text{ rule, for example. The assumption that all variables occurring in contexts are distinct from one another is silently preserved by the implicit proviso in rules that extend the context, where we rename the bound variable if it is already present.}
\]

Note that we use a generic \( \Gamma \) for the context appearing in these rules, whereas the reader may have expected this to be, for example, \( \Phi_{\alpha t} \) having schema \( S_{\alpha t} \) in the typing rules. In fact, we take a more liberal approach, where we pass to the rules any context that can be seen as a weakening of \( \Phi_{\alpha t} \); in other words, any \( \Gamma \) such that there exists a \( D \) for which \( rm^*_{\alpha t}(\Gamma) = \Phi_{\alpha t} \).

Suppose now, to fix ideas, that \( \Phi_{\alpha t} \vdash M : B \) holds. By convention, we implicitly assume that both \( B \) and \( M \) are well-formed, which means that \( \Phi_{\alpha t} \vdash \text{is\_tp} B \) and \( \Phi_{\alpha t} \vdash \text{is\_tm} M \). In fact, we can define functions \( rm^*_{\alpha, C} \) and \( rm^*_{\alpha, \text{tm}; x; C} \), use them to define strengthened contexts \( \Phi_{\alpha x} \) and \( \Phi_{\alpha} \), and apply the c-str rule to conclude the following:

1. \( \Phi_{\alpha x} := rm^*_{\alpha, C}(\Phi_{\alpha t}), \quad \Phi_{\alpha x} \text{ has schema } S_{\alpha x}, \quad \text{and } \Phi_{\alpha x} \vdash \text{is\_tm} M; \)
2. \( \Phi_{\alpha} := rm^*_{\alpha, \text{tm}; x; C}(\Phi_{\alpha t}), \quad \Phi_{\alpha} \text{ has schema } S_{\alpha}, \quad \text{and } \Phi_{\alpha} \vdash \text{is\_tp} B. \)
2.5. Generalized Contexts vs. Context Relations

As an alternative to using functions such as rm\textsuperscript{∗}\textsubscript{C} in item (1), we may adopt the more suggestive notation Φ\textsubscript{αx} ∼ Φ\textsubscript{αt}, using inference rules for the context relation corresponding to the graph of the function \(\lambda d.\text{case } d\text{ of is}\_\text{tp } α \mapsto \text{is}\_\text{tp } α \mid \text{is}\_\text{tm } x; x:C \mapsto \text{is}\_\text{tm } x\):

\[
\frac{}{\Phi\textsubscript{αx} \sim Φ\textsubscript{αt}} \frac{\Phi\textsubscript{αx} \sim Φ\textsubscript{αt}}{\frac{}{(\Phi\textsubscript{αx}, \text{is}\_\text{tp } α) \sim (Φ\textsubscript{αt}, \text{is}\_\text{tp } α)} \frac{}{(Φ\textsubscript{αx}, \text{is}\_\text{tm } x) \sim (Φ\textsubscript{αt}, \text{is}\_\text{tm } x; x:B)}}
\]

Similarly, an alternative to rm\textsuperscript{∗}\textsubscript{tm }x; x:C in item (2) is the following context relation:

\[
\frac{}{Φ\textsubscript{α} \sim Φ\textsubscript{αt}} \frac{}{(Φ\textsubscript{α}, \text{is}\_\text{tp } α) \sim (Φ\textsubscript{αt}, \text{is}\_\text{tp } α)} \frac{}{(Φ\textsubscript{α}, \text{is}\_\text{tm } x; x:B) \sim (Φ\textsubscript{αt}, \text{is}\_\text{tm } x; x:B)}
\]

The above two statements can now be restated using these relations. Given Φ\textsubscript{αt}, let Φ\textsubscript{αx} and Φ\textsubscript{α} be the unique contexts such that:

1. Φ\textsubscript{αx} ∼ Φ\textsubscript{αt}, Φ\textsubscript{αx} has schema S\textsubscript{αx}, and Φ\textsubscript{αx} ⊢ \text{is}\_\text{tm } M;
2. Φ\textsubscript{α} ∼ Φ\textsubscript{αt}, Φ\textsubscript{α} has schema S\textsubscript{α}, and Φ\textsubscript{α} ⊢ \text{is}\_\text{tp } B.

When stating and proving properties, we often relate two judgments to each other, where each one has its own context. For example, we may want to prove statements such as “if Φ\textsubscript{αx} ⊢ J\textsubscript{1} then Φ\textsubscript{αt} ⊢ J\textsubscript{2}.” The question is how we achieve that. In the benchmarks in this paper, we consider two approaches:

1. We reinterpret the statement in the smallest context that collects all relevant assumptions; we call this the generalized context approach (G). In this case, we reinterpret the above statement about J\textsubscript{1} in a context containing additional assumptions about typing, which in this case is Φ\textsubscript{αt}, yielding:

   “if Φ\textsubscript{αt} ⊢ J\textsubscript{1} then Φ\textsubscript{αt} ⊢ J\textsubscript{2}.”

2. We state how two (or more) contexts are related; we call this the context relations approach (R). Here, we define context relations such as those above and use them explicitly in the statements of theorems. In this case, we use Φ\textsubscript{αx} ∼ Φ\textsubscript{αt} yielding:

   “if Φ\textsubscript{αx} ⊢ J\textsubscript{1} and Φ\textsubscript{αx} ∼ Φ\textsubscript{αt} then Φ\textsubscript{αt} ⊢ J\textsubscript{2}.”

Note that here too we “minimize” the relations, in the sense of relating the smallest possible contexts where the relevant judgments make sense.

2.6. Context Promotion and Linear Extension of Contexts and Schemas

Another common idiom in meta-reasoning occurs when we have established a property for a particular context and we would like to use this property subsequently in a more general context. Assume that we have proven a lemma about types in context Φ\textsubscript{α} of the form “if Φ\textsubscript{α} ⊢ J\textsubscript{1} then Φ\textsubscript{α} ⊢ J\textsubscript{2}.” We now want to use this lemma in a proof about terms, that is where we have a context Φ\textsubscript{αx} and Φ\textsubscript{αx} ⊢ J\textsubscript{1}. We may need to promote this lemma, and prove: “if Φ\textsubscript{αx} ⊢ J\textsubscript{1} then Φ\textsubscript{αx} ⊢ J\textsubscript{2}.” We will see several examples of such promotion lemmas in Sect. 3.

Finally, to structure our subsequent discussion, it is useful to introduce some additional terminology regarding context relationships, where we use “relationship” in contrast to the more specific notion of “context relation.”
Linear extension of a declaration: a declaration $D_2$ is a linear extension of a declaration $D_1$, if every atom in the declaration $D_1$ is a member of the declaration $D_2$.

Linear extension of a schema: a schema $S_2$ is a linear extension of a schema $S_1$, if every declaration in $S_1$ is a linear extension of a declaration in $S_2$. For example $S_{\alpha t}$ is a linear extension of $S_{\alpha x}$.

Given a context $\Phi_1$ of schema $S_1$ and a context $\Phi_2$ of schema $S_2$ where $S_2$ is a linear extension of $S_1$, we say that $\Phi_2$ is a linear extension of $\Phi_1$ (i.e., linear context extension). Of course, sometimes declarations, schemas and contexts are not related linearly. For example, we may have a schema $S_2$ and a schema $S_3$ both of which are linear extensions of $S_1$; however, $S_2$ is not a linear extension of $S_3$ (or vice versa). In this case, we say $S_2$ and $S_3$ are non-linear extensions of each other and they share a most specific common fragment.

3. Benchmarks

In this section, we present several case studies establishing proofs of various properties of the lambda-calculus. We have structured this section around the different shapes and properties of contexts, namely:

1 Basic linear context extensions: We consider here contexts containing no alternatives. We refer to such contexts as basic. We discuss context membership and revisit structural properties such as weakening and strengthening.
2 Linear context extensions with alternative declarations.
3 Non-linear context extensions: We consider more complex relationships between contexts and discuss how our proofs involving weakening and strengthening change.
4 Order: We consider how the ordered structure of contexts impacts proofs relying on exchange.
5 Uniqueness: We consider here a case study which highlights how the issue of distinctness of all variable declarations in a context arises in proofs.
6 Substitution: Finally, we exhibit the fundamental properties of hypothetical and parametric substitution.

The benchmark problems are purposefully simple; they are designed to be easily understood so that one can quickly appreciate the capabilities and trade-offs of the different systems in which they can be implemented. Yet we believe they are representative of the issues and problems arising when encoding formal systems and reasoning about them. As we go along we discuss both the G approach and the R approach and comment on the trade-offs and differences in proofs depending on the chosen approach.

3.1. Basic Linear Context Extension

We concentrate in this section on contexts with simple schemas consisting of a single declaration. We aim to show the basic building blocks of reasoning over open terms: namely what a context looks like and the structure of an inductive proof. For the latter, we focus on the case analysis and, at the risk of being pedantic, the precise way in which the induction hypothesis is applied.
We start with a very simple judgment: *algorithmic equality* for the untyped lambda-calculus, written \((\text{aeq } M N)\), also known as *copy clauses*, see [Miller, 1991]. We say that two terms are algorithmically equal provided they have the same structure with respect to the constructors.

Algorithmic Equality

\[
\begin{aligned}
\Gamma \vdash \text{aeq } x x & \quad \text{ae}_c \\
\text{ae}_c & \quad \Gamma, \text{is}\_\text{tm } x; \text{aeq } x x \vdash \text{aeq } M N \\
\Gamma \vdash \text{aeq } (\text{lam } x. M) (\text{lam } x. N) & \quad \text{ae}_c \\
\Gamma \vdash \text{aeq } M_1 N_1 & \Gamma \vdash \text{aeq } M_2 N_2 \quad \text{ae}_c \\
\Gamma \vdash \text{aeq } (\text{app } M_1 M_2) (\text{app } N_1 N_2) & \quad \text{ae}_c 
\end{aligned}
\]

The context schemas needed for reasoning about this judgment are the following:

**Context Schemas**

\[
\begin{aligned}
S_x & := \text{is}\_\text{tm } x \\
S_{xa} & := \text{is}\_\text{tm } x; \text{aeq } x x
\end{aligned}
\]

where a context \(\Phi_{xa}\) satisfying \(S_{xa}\) is the smallest possible context in which such an equality judgment can hold. Thus, as discussed in the previous section, when writing judgment \(\Phi_{xa} \vdash \text{aeq } M N\), we assume that \(\Phi_{xa} \vdash \text{is}\_\text{tm } M\) and \(\Phi_{xa} \vdash \text{is}\_\text{tm } N\) hold, and thus also \(\Phi_x \vdash \text{is}\_\text{tm } M\) and \(\Phi_x \vdash \text{is}\_\text{tm } N\) hold by employing an implicit c-str (using \(\text{rm}_\text{aeq } x x\)). We note that both contexts \(\Phi_x\) and \(\Phi_{xa}\) are simple contexts consisting of one declaration block. Moreover, \(S_x\) is a sub-schema of \(S_{xa}\) and therefore the context \(\Phi_{xa}\) is a linear extension of the context \(\Phi_x\).

In view of the pedagogical nature of this subsection and also of the content of Sect. 3.3, which will build on this example, we start with a straightforward property: algorithmic equality is reflexive. This property should follow by induction on \(M\) (via the well-formed term judgment, which is not shown, but uses the obvious subset of the rules in Sect. 2.4). However, the question of which contexts the two judgments should be stated in arises immediately; recall that we want to prove "if \(\Gamma_1 \vdash \text{is}\_\text{tm } M\) then \(\Gamma_2 \vdash \text{aeq } M M\)." \(\Gamma_2\) should be a context satisfying \(S_{xa}\) since the definition of this schema came directly from the inference rules of this judgment. The form that \(\Gamma_1\) should take is less clear. The main requirement comes from the base case, where we must know that for every assumption \(\text{is}\_\text{tm } x\) in \(\Gamma_1\) there exists a corresponding assumption \(\text{aeq } x x\) in \(\Gamma_2\). The answer differs depending on whether we choose the R approach or the G approach. We discuss each in turn below.

### 3.1.1. Context Relations, R Version

The relation needed here is \(\Phi_x \sim \Phi_{xa}\), defined as follows:

**Context Relation**

\[
\begin{aligned}
\Phi_x \sim \Phi_{xa} & \quad \text{crel}_e \\
\Phi_x, \text{is}\_\text{tm } x \sim \Phi_{xa}, \text{is}\_\text{tm } x; \text{aeq } x x & \quad \text{crel}_{xa}
\end{aligned}
\]

Note that \(\text{is}\_\text{tm } x\) will occur in \(\Phi_x\) in sync with an assumption block containing \(\text{is}\_\text{tm } x; \text{aeq } x x\) in \(\Phi_{xa}\). This is a property which needs to be established separately, so at the risk of redundancy, we state it as a “member” lemma.
Lemma 6 (Context Membership).
\[ \Phi \sim \Phi_{xa} \text{ implies that } \text{is}\_tm\ x \in \Phi \text{ iff } \text{is}\_tm\ x; \text{aeq } x \in \Phi_{xa}. \]

Proof. By induction on \( \Phi \sim \Phi_{xa} \). \( \square \)

Theorem 7 (Admissibility of Reflexivity, R Version). Assume \( \Phi \sim \Phi_{xa} \).
If \( \Phi \vdash \text{is}\_tm\ M \) then \( \Phi_{xa} \vdash \text{aeq } M \ M \).

Proof. By induction on the derivation \( D :: \Phi \vdash \text{is}\_tm\ M \).
Case:
\[
D = \frac{\text{is}\_tm\ x \in \Phi \quad \text{tm}_v}{\Phi \vdash \text{is}\_tm\ x} \quad \text{by rule premise}
\]
\[
is\_tm\ x \in \Phi_x
\]
\[
is\_tm\ x; \text{aeq } x \in \Phi_{xa}
\]
\[
\Phi_{xa} \vdash \text{aeq } x \ x
\]

Case:
\[
D_1 = \frac{\Phi_x \vdash \text{is}\_tm\ M_1}{\Phi_x \vdash \text{is}\_tm\ (\text{app } M_1 M_2)} \quad \text{sub-derivation } D_1
\]
\[
D_2 = \frac{\Phi_x \vdash \text{is}\_tm\ M_2}{\Phi_x \vdash \text{is}\_tm\ (\text{app } M_1 M_2)} \quad \text{sub-derivation } D_2
\]
\[
\Phi_x \vdash \text{is}\_tm\ M_1
\]
\[
\Phi_{xa} \vdash \text{aeq } M_1 M_1
\]
\[
\Phi_x \vdash \text{is}\_tm\ M_2
\]
\[
\Phi_{xa} \vdash \text{aeq } M_2 M_2
\]
\[
\Phi_{xa} \vdash \text{aeq } (\text{app } M_1 M_2) (\text{app } M_1 M_2)
\]

Case:
\[
D' = \frac{\Phi_x, \text{is}\_tm\ x \vdash \text{is}\_tm\ M}{\Phi_x \vdash \text{is}\_tm\ (\text{lam } x. M)} \quad \text{sub-derivation } D'
\]
\[
\Phi_x, \text{is}\_tm\ x \vdash \text{is}\_tm\ M
\]
\[
\Phi_x \sim \Phi_{xa}
\]
\[
(\Phi_x, \text{is}\_tm\ x) \sim (\Phi_{xa}, \text{is}\_tm\ x; \text{aeq } x \ x)
\]
\[
\Phi_{xa}, \text{is}\_tm\ x; \text{aeq } x \ x \vdash \text{aeq } M \ M
\]
\[
\Phi_{xa} \vdash \text{aeq } (\text{lam } x. M) (\text{lam } x. M)
\]

To be precise about the instantiation of the inductions hypothesis, consider the following general statement of the theorem (and induction hypothesis):

\[ \text{forall } \Phi_1, \Phi_2, N, \text{ if } \Phi_1 \sim \Phi_2 \text{ and } \Phi_1 \vdash \text{is}\_tm\ N \text{ then } \Phi_2 \vdash \text{aeq } N \ N. \]

In the \( \text{tm}_l \) case above, \( \Phi_1 \), \( \Phi_2 \), and \( N \) in the conclusion of this case are \( \Phi_x \), \( \Phi_{xa} \), and \( \text{lam } x. M \), respectively, while the instantiations of \( \Phi_1 \), \( \Phi_2 \), and \( N \) for the induction hypothesis are \( (\Phi_x, \text{is}\_tm\ x) \), \( (\Phi_{xa}, \text{is}\_tm\ x; \text{aeq } x \ x) \), and \( M \), respectively.
3.1.2. Generalized Contexts, G Version In this example, since $S_{xa}$ includes all assumptions in $S_x$, $S_{xa}$ will serve as the schema of our generalized context.

Theorem 8 (Admissibility of Reflexivity, G Version). If $\Phi_{xa} \vdash \text{is_tm } M$ then $\Phi_{xa} \vdash \text{aeq } M M$.

Proof. By induction on the derivation $D : \Phi_{xa} \vdash \text{is_tm } M$.

Case:

\[ D = \frac{\text{is_tm } x \in \Phi_{xa}}{\Phi_{xa} \vdash \text{is_tm } x} \]

- $\text{is_tm } x \in \Phi_{xa}$ by rule premise
- $\Phi_{xa}$ contains block $(\text{is_tm } x; \text{aeq } x x)$ by definition of $S_{xa}$
- $\Phi_{xa} \vdash \text{aeq } x x$ by rule $ae_v$

Case:

\[ D = \frac{\Phi_{xa} \vdash \text{is_tm } M_1 \quad \Phi_{xa} \vdash \text{is_tm } M_2}{\Phi_{xa} \vdash \text{is_tm } (\text{app } M_1 M_2)} \]

- $\Phi_{xa} \vdash \text{aeq } M_1 M_1$ by IH on $D_1$
- $\Phi_{xa} \vdash \text{aeq } M_2 M_2$ by IH on $D_2$
- $\Phi_{xa} \vdash \text{aeq } (\text{app } M_1 M_2) (\text{app } M_1 M_2)$ by rule $ae_a$

Case:

\[ D = \frac{\Phi_{xa}, \text{is_tm } x \vdash \text{is_tm } M}{\Phi_{xa} \vdash \text{is_tm } (\text{lam } x. M)} \]

- $\Phi_{xa}, \text{is_tm } x; \text{aeq } x x \vdash \text{is_tm } M$ by $d-wk$ on $D'$
- $\Phi_{xa}, \text{is_tm } x; \text{aeq } x x \vdash \text{aeq } M M$ by IH
- $\Phi_{xa} \vdash \text{aeq } (\text{lam } x. M) (\text{lam } x. M)$ by rule $ae_l$

We again consider the general statement of the theorem (and induction hypothesis):

\[
\text{forall } \Phi, N, \text{ if } \Phi \vdash \text{is_tm } N \text{ then } \Phi \vdash \text{aeq } N N
\]

In this version of the $\text{tm}_l$ case, $\Phi$ and $N$ in the conclusion are $\Phi_{xa}$ and $(\text{lam } x. M)$, respectively, while the instantiations of $\Phi$ and $N$ for the induction hypothesis are $(\Phi_{xa}, \text{is_tm } x; \text{aeq } x x)$ and $M$, respectively.

Note that the application cases of Theorems 7 and 8 are the same except for the context used for the well-formed term judgment. The lambda case here, on the other hand, requires an additional weakening step. In particular, $d-wk$ is used to add an atom to form the declaration needed for schema $S_{xa}$. The context before applying weakening does not satisfy this schema, and the induction hypothesis cannot be applied until it does.
We end this subsection, stating the remaining properties needed to establish that algorithmic equality is indeed a congruence, which we will prove in Sect. 3.3. Since the proof involves only $\Phi_{xa}$, the two approaches (R & G) collapse.

**Lemma 9 (Context Inversion).** If $aeq M N \in \Phi_{xa}$ then $M = N$.

*Proof.* Induction on $aeq M N \in \Phi_{xa}$. □

**Theorem 10 (Admissibility of Symmetry and Transitivity).**

1. If $\Phi_{xa} \vdash aeq M N$ then $\Phi_{xa} \vdash aeq N M$.
2. If $\Phi_{xa} \vdash aeq M L$ and $\Phi_{xa} \vdash aeq L N$ then $\Phi_{xa} \vdash aeq M N$.

*Proof.* Induction on the given derivation using Lemma 9 in the variable case. □

3.2. Linear Context Extensions with Alternative Declarations

We extend our algorithmic equality case study to the polymorphic lambda-calculus, highlighting the situation where judgments induce context schemas with *alternatives*. We accordingly add the judgment for *type equality*, $atp A B$, noting that the latter can be defined independently of term equality. In other words $aeq M N$ depends on $atp A B$, but not vice versa. In addition to $S_\alpha$ and $S_{ax}$ introduced in Sect. 2, the following new context schemas are also used here:

$$
S_{atp} := \text{is}_\text{tp} \alpha; \text{atp} \alpha \alpha \\
S_{aeq} := \text{is}_\text{tp} \alpha; \text{atp} \alpha \alpha + \text{is}_\text{tm} x; aeq x 
$$

The rules for the two equality judgments extend those given in Sect. 3.1. The additional rules are stated below.

**Algorithmic Equality for the Polymorphic Lambda-Calculus**

\[
\begin{align*}
\Gamma, \text{is}_\text{tp} \alpha; \text{atp} \alpha \alpha & \vdash aeq M N \quad \text{ae}_{\text{ql}} \\
\Gamma & \vdash aeq (\text{tlam} \alpha. M) (\text{tlam} \alpha. N) \\
\Gamma & \vdash aeq M N \quad \Gamma & \vdash \text{atp} A B \quad \text{ae}_{\text{ta}} \\
\Gamma & \vdash aeq (\text{tapp} M A) (\text{tapp} N B) \\
\text{atp} \alpha \alpha & \in \Gamma \\
\Gamma & \vdash \text{atp} \alpha \alpha \quad \text{at}_{\alpha} \\
\Gamma, \text{is}_\text{tp} \alpha; \text{atp} \alpha \alpha & \vdash \text{atp} A B \quad \text{at}_{\text{ai}} \\
\Gamma & \vdash \text{atp} (\text{all} \alpha. A) (\text{all} \alpha. B) \\
\Gamma & \vdash \text{atp} (\text{arr} A_1 A_2) (\text{arr} B_1 B_2) \quad \text{at}_{\alpha} \\
\end{align*}
\]

We show again the admissibility of reflexivity. We start with the G version this time.

3.2.1. G Version We first state and prove the admissibility of reflexivity for types, which we then use in the proof of admissibility of reflexivity for terms. The schema for the
generalized context for the former is $S_{\text{atp}}$ since the statement and proof do not depend on terms. The schema for the latter is $S_{\text{aeq}}$.

**Theorem 11 (Admissibility of Reflexivity for Types, G Version).** If $\Phi_{\text{atp}} \vdash \text{is}_\text{tp} \ A$ then $\Phi_{\text{atp}} \vdash \text{atp} \ A \ A$.

The proof is exactly the same as the proof of Theorem 8, modulo replacing $\text{app}$ and $\text{lam}$ with $\text{arr}$ and $\text{all}$, respectively, and using the corresponding rules.

As we have already mentioned in Sect. 2, it is often the case that we need to appeal to a lemma in a context that is different from the context where it was proved. A concrete example is the above lemma, which is stated in context $\Phi_{\text{atp}}$, but is needed in the proof of the next theorem in the larger context $\Phi_{\text{aeq}}$. To illustrate, we state and prove the necessary promotion lemma here.

**Lemma 12 (G-Promotion for Type Reflexivity).** If $\Phi_{\text{aeq}} \vdash \text{is}_\text{tp} \ A$ then $\Phi_{\text{aeq}} \vdash \text{atp} \ A \ A$.

**Proof.**

- $\Phi_{\text{aeq}} \vdash \text{is}_\text{tp} \ A$ by assumption
- $\Phi_{\text{atp}} \vdash \text{is}_\text{tp} \ A$ by $c\text{-str}$
- $\Phi_{\text{atp}} \vdash \text{atp} \ A \ A$ by Theorem 11
- $\Phi_{\text{aeq}} \vdash \text{atp} \ A \ A$ by $c\text{-wk}$

In general, proofs of promotion lemmas require applications of $c\text{-str}$ and $c\text{-wk}$ which perform a uniform modification to an entire context. In contrast, the abstraction cases in proofs such as the lambda case of Theorem 8 require $d\text{-wk}$ to add atoms to a single declaration. The particular function used here is $\text{rm}_{\text{aeq}} \ x : x \ e q \ x \ x$, which drops an entire alternative from $\Phi_{\text{aeq}}$ to obtain $\Phi_{\text{atp}}$ and leaves the other alternative unchanged. The combination of $c\text{-str}$ and $c\text{-wk}$ in proofs of promotion lemmas is related to subsumption; see [Harper and Licata, 2007].

Note that we could omit Theorem 11 and instead prove Lemma 12 directly, removing the need for a promotion lemma. For modularity purposes, we adopt the approach that we state each theorem in the smallest possible context in which it is valid. This particular lemma, for example, will be needed in an even bigger context than $\Phi_{\text{aeq}}$ in Sect. 3.3. In general, we do not want the choice of context in the statement of a lemma to depend on later theorems whose proofs require this lemma. Instead, we choose the smallest context and state and prove promotion lemmas where needed.

**Theorem 13 (Admissibility of Reflexivity for Terms, G Version).** If $\Phi_{\text{aeq}} \vdash \text{is}_\text{tm} \ M$ then $\Phi_{\text{aeq}} \vdash \text{aeq} \ M \ M$.

**Proof.** Again, the proof is by induction on the given well-formed term derivation, in this case $D : \Phi_{\text{aeq}} \vdash \text{is}_\text{tm} \ M$, and is similar to the proof of Theorem 8. We show the case for application of terms to types.
Case:

\[
D = \Phi_{\text{eqg}} \vdash \text{is} \cdot \text{tm} \ M \quad \Phi_{\text{eqg}} \vdash \text{is} \cdot \text{tp} \ A \\
\Phi_{\text{eqg}} \vdash \text{is} \cdot \text{tm} (\text{tapp} M A)
\]

\[
\Phi_{\text{eqg}} \vdash \text{ameg} M M \quad \text{by IH on } D_1 \\
\Phi_{\text{eqg}} \vdash \text{atp} A A \quad \text{by Lemma 12 on conclusion of } D_2 \\
\Phi_{\text{eqg}} \vdash \text{ameg} (\text{tapp} M A) (\text{tapp} M A) \quad \text{by rule aet_a}
\]

3.2.2. R Version We introduce four context relations \( \Phi_{\alpha} \sim \Phi_{\text{atp}} \), \( \Phi_{\alpha x} \sim \Phi_{\text{aeq}} \), \( \Phi_{\alpha x} \sim \Phi_{\alpha} \), and \( \Phi_{\text{aeq}} \sim \Phi_{\text{atp}} \). We define the first two as follows (where we omit the inference rules for the base cases).

Context Relations

\[
\Phi_{\alpha} \sim \Phi_{\text{atp}} \\
\Phi_{\alpha}, \text{is} \cdot \text{tp} \alpha \sim \Phi_{\text{atp}}, \text{is} \cdot \text{tp} \alpha ; \text{atp} \alpha \alpha \\
\Phi_{\alpha x}, \text{is} \cdot \text{tm} x \sim \Phi_{\text{eqg}}, \text{is} \cdot \text{tm} x ; \text{aeq} \alpha x \\
\Phi_{\alpha x}, \text{is} \cdot \text{tp} \alpha \sim \Phi_{\text{eqg}}, \text{is} \cdot \text{tp} \alpha ; \text{atp} \alpha \alpha
\]

Note that \( \Phi_{\alpha x} \sim \Phi_{\text{eqg}} \) is the extension of \( \Phi_{\alpha} \sim \Phi_{\text{eqg}} \) with one additional case for equality for types. Again, we remark on our policy to use the smallest contexts possible for modularity reasons. Otherwise, we could have omitted the \( \Phi_{\alpha} \sim \Phi_{\text{atp}} \) relation, and stated the next theorem using \( \Phi_{\alpha x} \sim \Phi_{\text{eqg}} \). We also omit the (obvious) inference rules defining \( \Phi_{\alpha x} \sim \Phi_{\alpha} \) and \( \Phi_{\text{eqg}} \sim \Phi_{\text{atp}} \), and instead note that they correspond to the graphs of the following two functions, respectively, which simply remove one of the two schema alternatives:

\[
\text{rm}^{*}_{\text{is} \cdot \text{tm} x} = \lambda d. \text{case } d \text{ of } \text{is} \cdot \text{tp} \alpha \mapsto \text{is} \cdot \text{tp} \alpha \mid \text{is} \cdot \text{tm} x \mapsto . \\
\text{rm}^{*}_{\text{is} \cdot \text{tm} x ; \text{aeq} x x} = \lambda d. \text{case } d \text{ of } \text{is} \cdot \text{tp} \alpha ; \text{atp} \alpha \alpha \mapsto \text{is} \cdot \text{tp} \alpha ; \text{atp} \alpha \alpha \mid \text{is} \cdot \text{tm} x ; \text{aeq} x x \mapsto .
\]

We start with the theorem for types again, whose proof is similar to the R version of the previous example (Theorem 7) and is therefore omitted.

**Theorem 14 (Admissibility of Reflexivity for Types, R Version).** Let \( \Phi_{\alpha} \sim \Phi_{\text{eqg}} \). If \( \Phi_{\alpha} \vdash \text{is} \cdot \text{tp} A \) then \( \Phi_{\text{eqg}} \vdash \text{atp} A A \).

**Lemma 15 (Relational Strengthening).** Let \( \Phi_{\alpha x} \sim \Phi_{\text{eqg}} \). Then there exist contexts \( \Phi_{\alpha} \) and \( \Phi_{\text{eqg}} \) such that \( \Phi_{\alpha x} \sim \Phi_{\alpha} \), \( \Phi_{\text{eqg}} \sim \Phi_{\text{atp}} \), and \( \Phi_{\alpha} \sim \Phi_{\text{atp}} \).

**Proof.** By induction on the given derivation of \( \Phi_{\alpha x} \sim \Phi_{\text{eqg}} \). \( \square \)

We again need a promotion lemma, this time involving the context relation.

**Lemma 16 (R-Promotion for Type Reflexivity).** Let \( \Phi_{\alpha x} \sim \Phi_{\text{eqg}} \). If \( \Phi_{\alpha x} \vdash \text{is} \cdot \text{tp} A \) then \( \Phi_{\text{eqg}} \vdash \text{atp} A A \).

**Proof.**

\( \Phi_{\alpha x} \vdash \text{is} \cdot \text{tp} A \) \quad \text{by assumption}

**Theorem 17 (Admissibility of Reflexivity for Terms, R Version).** Let $\Phi_{\alpha x} \sim \Phi_{\alpha q}$. If $\Phi_{\alpha x} \vdash \text{is}_\text{tm} \ M$ then $\Phi_{\alpha q} \vdash \text{aeq} \ M \ M$.

*Proof.* Again, the proof is by induction on the given derivation. Most cases are similar to the analogous cases in the proof of the R version for the monomorphic case (Theorem 7) and the G version for types in the polymorphic case (Theorem 11). We show again the case for application of terms to types to compare with the G version.

**Case:**

$\mathcal{D} = \Phi_{\alpha x} \vdash \text{is}_\text{tm} \ M \ \Phi_{\alpha x} \vdash \text{is}_\text{tp} \ A$ \hspace{1cm} $\Phi_{\alpha x} \vdash \text{is}_\text{tm} (\text{tapp} \ M \ A)$

\[ \begin{align*}
\Phi_{\alpha x} & \sim \Phi_{\alpha q} & \text{by assumption} \\
\Phi_{\alpha x} & \vdash \text{is}_\text{tm} \ M & \text{sub-derivation } \mathcal{D}_1 \\
\Phi_{\alpha q} & \vdash \text{aeq} \ M \ M & \text{by IH} \\
\Phi_{\alpha x} & \vdash \text{is}_\text{tp} \ A & \text{sub-derivation } \mathcal{D}_2 \\
\Phi_{\alpha q} & \vdash \text{atp} \ A \ A & \text{by Lemma 16} \\
\Phi_{\alpha q} & \vdash \text{aeq} (\text{tapp} \ M \ A) (\text{tapp} \ M \ A) & \text{by rule } \text{ae}_{\text{ta}}
\end{align*} \]

### 3.3. Non-Linear Context Extensions

We return to the untyped lambda-calculus of Sect. 3.1 and establish the equivalence between the algorithmic definition of equality defined previously, and declarative equality $\Phi_{\alpha d} \vdash \text{deq} \ M \ N$, which includes reflexivity, symmetry and transitivity in addition to the congruence rules.$^\dagger$

---

$^\dagger$ We acknowledge that this definition of declarative equality has a degree of redundancy: the assumption $\text{deq} \ x \ x$ in rule $\text{de}$$^a$ is not needed, since rule $\text{de}_x$ plays the variable role. However, it yields an interesting generalized context schema, which exhibits issues that would otherwise require more complex case studies.
Declarative Equality

\[
\begin{align*}
\Gamma ⊢ deq x x & \quad \text{de}_v \\
\Gamma ⊢ deq M N & \quad \text{de}_l \\
\Gamma ⊢ deq (\text{app } M_1 M_2) (\text{app } N_1 N_2) & \quad \text{de}_a
\end{align*}
\]

Context Schema \( S_{xd} := \text{is}_\text{tm } x; \text{deq } x x \)

We now investigate the interesting part of the equivalence, namely that when we have a proof of \( (\text{deq } M N) \) then we also have a proof of \( (\text{aeq } M N) \). We show the G version first.

3.3.1. G Version Here, a generalized context must combine the atoms of \( \Phi_{xa} \) and \( \Phi_{xd} \) into one declaration:

Generalized Context Schema \( S_{da} := \text{is}_\text{tm } x; \text{deq } x x; \text{aeq } x x \)

The following lemma promotes Theorems 8 and 10 to the “bigger” generalized context.

Lemma 18 (G-Promotion for Reflexivity, Symmetry, and Transitivity).

1. If \( \Phi_{da} ⊢ \text{is}_\text{tm } M \), then \( \Phi_{da} ⊢ \text{aeq } M M \).
2. If \( \Phi_{da} ⊢ \text{aeq } M N \), then \( \Phi_{da} ⊢ \text{aeq } N M \).
3. If \( \Phi_{da} ⊢ \text{aeq } M L \) and \( \Phi_{da} ⊢ \text{aeq } LN \), then \( \Phi_{da} ⊢ \text{aeq } M N \).

Proof. Similar to the proof of Theorem 12 where the application of \( c\text{-str} \) transforms a context \( \Phi_{da} \) to \( \Phi_{xa} \) by considering each block of the form \( \text{(is}_\text{tm } x; \text{deq } x x; \text{aeq } x x) \) and removing \( \text{(deq } x x) \).

Theorem 19 (Completeness, G Version).

If \( \Phi_{da} ⊢ \text{deq } M N \) then \( \Phi_{da} ⊢ \text{aeq } M N \).

Proof. By induction on the derivation \( D :: \Phi_{da} ⊢ \text{deq } M N \). We only show some cases.

Case:

\[
D = \text{de}_r \quad \Phi_{da} ⊢ \text{deq } M M \quad \text{by (implicit) assumption}
\]

\[
\Phi_{da} ⊢ \text{is}_\text{tm } M \\
\Phi_{da} ⊢ \text{aeq } M M \quad \text{by Lemma 18 (1)}
\]

Case:

\[
D = \text{de}_l \quad \Phi_{da} ⊢ \text{deq } M L \quad \Phi_{da} ⊢ \text{deq } L N \\
\Phi_{da} ⊢ \text{deq } M N \quad \text{by Lemma 18 (3)}
\]
\[ \Phi_{da} \vdash aeq \ M \ L \ \text{and} \ \Phi_{da} \vdash aeq \ L \ N \] by IH on \( D_1 \) and \( D_2 \)

\[ \Phi_{da} \vdash aeq \ M \ N \] by Lemma 18 (3)

Case:

\[ D = \frac{\Phi_{da} \vdash is\ tm \ x; deq \ x \ x \vdash deq \ M \ N}{deq} \]

\[ \Phi_{da} \vdash \ is\ tm \ x; deq \ x \ x \vdash deq \ M \ N \] by \( d-wk \) on \( D' \)

\[ \Phi_{da} \vdash \ is\ tm \ x; deq \ x \ x \vdash aeq \ M \ N \] by IH

\[ \Phi_{da} \vdash \ aeq \ (lam \ x. \ M) \ (lam \ x. \ N) \] by rule \( ae \)

The symmetry case is not shown, but also requires promotion, via Lemma 18 (2). Note that the \( de \) case requires both \( d-str \) and \( d-wk \). In contrast, the binder cases for the \( G \) versions of the previous examples (Theorems 8, 11, and 13) required only \( d-wk \). The need for both arises from the fact that the generalized context is a non-linear extension of two contexts, i.e., it is not the same as either one of the two contexts it combines.

3.3.2. \( R \) Version The context relation required here is \( \Phi_{xa} \sim \Phi_{xd} \):

\[ \text{Context Relation} \]

\[ \Phi_{xa} \sim \Phi_{xd} \]

\[ \Phi_{xa}, \ is\ tm \ x; aeq \ x \ x \sim \Phi_{xd}, \ is\ tm \ x; deq \ x \ x \] by \( crel_{ad} \)

As in Sect. 3.2, we need the appropriate promotion lemma, which again requires a relation strengthening lemma:

**Lemma 20 (Relational Strengthening).** Let \( \Phi_{xa} \sim \Phi_{xd} \). Then there exists a context \( \Phi_x \) such that \( \Phi_x \sim \Phi_{xa} \).

**Lemma 21 (R-Promotion for Reflexivity).** Let \( \Phi_{xa} \sim \Phi_{xd} \). If \( \Phi_{xd} \vdash is\ tm \ M \) then \( \Phi_{xa} \vdash aeq \ M \ M \).

The proofs are analogous to Lemmas 15 and 16, with the proof of Lemma 21 requiring Lemma 20.

**Theorem 22 (Completeness, \( R \) Version).** Let \( \Phi_{xa} \sim \Phi_{xd} \). If \( \Phi_{xd} \vdash deq \ M \ N \) then \( \Phi_{xa} \vdash aeq \ M \ N \).

**Proof.** By induction on the derivation \( D : \Phi_{xd} \vdash deq \ M \ N \).

Case:

\[ D = \frac{\Phi_{xd} \vdash deq \ M \ M \ }{de_r} \]

\[ \Phi_{xd} \vdash is\ tm \ M \] by (implicit) assumption

\[ \Phi_{xa} \vdash aeq \ M \ M \] by Theorem 21
A. Felty, A. Momigliano, and B. Pientka

Case:

\[ D = \frac{\Phi_{xd} \vdash deq M L \quad \Phi_{xd} \vdash deq L N}{\Phi_{xd} \vdash deq M N} \text{ deq} \]

\( \Phi_{xa} \vdash \text{aeq } M L \) and \( \Phi_{xa} \vdash \text{aeq } L N \) by IH on \( D_1 \) and \( D_2 \)

\( \Phi_{xa} \vdash \text{aeq } M N \) by Theorem 10 (2)

Case:

\[ D' = \frac{\Phi_{xd} \vdash \text{is_tm } x; deq x x \vdash deq (\text{lam } x. M) (\text{lam } x. N)}{deq} \]

\( \Phi_{xa} \sim \Phi_{xd} \) by assumption

\( \Phi_{xa} \vdash \text{is_tm } x; \text{aeq } x x \sim \Phi_{xd} \vdash \text{is_tm } x; \text{deq } x x \) by rule \( crel_{av} \)

\( \Phi_{za} \vdash \text{aeq } (\text{lam } x. M) (\text{lam } x. N) \) by IH on \( D' \)

Only one promotion lemma is required in this proof, for the reflexivity case (which requires one occurrence each of \( c-str \) and \( c-wk \)), and no strengthening or weakening is needed in the lambda case (thus no occurrences of \( d-str/wk \) in this proof). In contrast, the proof of the G version of this theorem (Theorem 19) uses 3 occurrences of each of \( c-str \) and \( c-wk \) via promotion Lemma 18 and one occurrence each of \( d-str \) and \( d-wk \) in the lambda case.

3.4. Order

A consequence of viewing contexts as sequences is that order comes into play, and therefore the need to consider exchanging the elements of a context. This happens when, for example, a judgment singles out a particular occurrence of an assumption in head position. We exemplify this with a “parallel” substitution property for algorithmic equality, stated below. The proof also involves some slightly more sophisticated reasoning about names in the variable case than previously observed. Furthermore, note that this substitution property does not “come for free” in a HOAS encoding in the way, for example, that type substitution (Lemma 25) does.

Theorem 23 (Pairwise Substitution). If \( \Phi_{xa} \vdash \text{is_tm } x; \text{aeq } x x \vdash \text{aeq } M_1 M_2 \) and \( \Phi_{za} \vdash \text{aeq } N_1 N_2 \), then \( \Phi_{xa} \vdash \text{aeq } ([N_1/x]M_1) ([N_2/x]M_2) \).

Proof. By induction on the derivation \( D :: \Phi_{xa} \vdash \text{is_tm } x; \text{aeq } x x \vdash \text{aeq } M_1 M_2 \) and inversion on \( \Phi_{xa} \vdash \text{aeq } N_1 N_2 \). We show two cases.

Case:

\[ D = \frac{\Phi_{xa} \vdash \text{aeq } y y \in \Phi_{xa} \vdash \text{is_tm } x; \text{aeq } x x \vdash \text{aeq } y y}{\Phi_{xa} \vdash \text{aeq } (\text{[N}_1/x\text{]}y) (\text{[N}_2/x\text{]}y)} \text{ aeq} \]

We need to establish \( \Phi_{xa} \vdash \text{aeq } (\text{[N}_1/x\text{]}y) (\text{[N}_2/x\text{]}y) \).
Sub-case: \( y = x \): Applying the substitution to the above judgment, we need to show \( \Phi_{xa} \vdash \text{aeq } N_1 N_2 \), which we have.

Sub-case: \( \text{aeq } y y \in \Phi_{xa} \), for \( y \neq x \). Applying the substitution in this case gives us \( \Phi_{xa} \vdash \text{aeq } y y \), which we have by assumption.

Case:

\[
\Phi_{xa} \vdash \text{is tm } x; \text{aeq } x \| x \vdash \text{aeq } M_1 M_2
\]

by \( \text{exc} \) on \( \mathcal{D}' \)

We remark that there are more general ways to formulate properties such as Theorem 23 that do not require (on paper) exchange; for example,

If \( \Phi_{xa}, \text{is tm } y; \text{aeq } y y, \Phi'_{xa} \vdash \text{aeq } M_1 M_2 \) and \( \Phi_{xa} \vdash \text{aeq } N_1 N_2 \), then \( \Phi_{xa}, \Phi'_{xa} \vdash \text{aeq } ([N_1/x]M_1) ([N_2/x]M_2) \).

The proof of the latter statement has a similar structure to the previous one, except that it uses \( \text{d-wk} \) in the first variable sub-case, while the binding case does not employ any structural property to apply the induction hypothesis, by taking \( \Phi''_{xa}, \text{is tm } y; \text{aeq } y y \) as \( \Phi'_{xa} \). While this works well in a paper and pencil style, it is much harder to mechanize, since it brings in reasoning about appending and splitting lists that are foreign to the matter at hand.

We conclude by noting that there are examples where exchange cannot be applied, since the dependency proviso is not satisfied. Cases in point are substitution lemmas for dependent types. Here, other encoding techniques must be used, as explored in [Crary, 2009].

3.5. Uniqueness

Uniqueness of context variables plays an unsurprisingly important role in proving type uniqueness, i.e. every lambda-term has a unique type. For the sake of this discussion it is enough to consider the monomorphic case, where abstractions include type annotations on bound variables, and types consist only of a ground type and a function arrow.

\[
\text{Terms} \quad M \ ::= \ y \mid \text{lam } x : A \mid \text{app } M_1 M_2
\]

\[
\text{Types} \quad A \ ::= \ i \mid \text{arr } A B
\]

The typing rules are the obvious subset of the ones presented in Sect. 2, modified to take a type superscript on bound variables, yielding:

\[
\text{Context Schema} \quad S_i := \text{is tm } x : A
\]
The statement of the theorem requires only a single context and thus there is no distinction to be made between the R and G versions. Recall that we assume that eigenvariables in different blocks in a context satisfying the schema are distinct from each other.

**Theorem 24 (Type Uniqueness).** If $\Phi_t \vdash M : A$ and $\Phi_t \vdash M : B$ then $A = B$.

**Proof.** The proof is by induction on the first derivation and inversion on the second. We show only the variable case where uniqueness plays a central role.

Case:

$$D = \frac{x:A \in \Phi_t}{\Phi_t \vdash x : A} of_v$$

We know that $x:A \in \Phi_t$ by rule of $v$. By definition, $\Phi_t$ contains block $(is_{tm} x:x:A)$. Moreover, we know $\Phi_t \vdash x : B$ by assumption. By inversion using rule of $v$, we know that $x:B \in \Phi_t$, which means that $\Phi_t$ contains block $(is_{tm} x:x:B)$. Since all assumptions about $x$ occur uniquely, these must be the same block. Thus $A$ must be identical to $B$.

### 3.6. Substitution

In this section we address the interaction of the substitution property with context reasoning. It is well known and rightly advertised that substitution lemmas come “for free” in HOAS encodings, since substitutivity is just a by-product of hypothetical-parametric judgments. We refer the reader to [Pfenning, 2001] for more details. A classic example is the proof of type preservation for a functional programming language, where a lemma stating that substitution preserves typing is required in every case that involves a $\beta$-reduction. However, this example theorem is unduly restrictive since functional programs are closed expressions; in fact, the proof proceeds by induction on (closed) evaluation and inversion on typing, hence only addressing contexts in a marginal way. We thus discuss a similar proof for an evaluation relation that “goes under a lambda” and we choose parallel reduction, as it is a standard relation also used in other important case studies such as the Church-Rosser theorem. The context schema and relevant rules are below.

**Parallel Reduction**

\[
\begin{align*}
\frac{x \sim x \in \Gamma}{\Gamma \vdash x \sim x} & \quad \frac{\Gamma, is_{tm} x ; x \sim x \vdash M \sim N}{\Gamma \vdash \text{lam} x. M \sim \text{lam} x. N} \\
\Gamma, is_{tm} x ; x \sim x \vdash M \sim M' & \quad \Gamma, N \sim N' \vdash (\text{app} (\text{lam} x. M) N) \sim [N'/x]M' \\
\frac{\Gamma \vdash M \sim M'}{\Gamma \vdash \text{app} M N \sim (\text{app} M' N')} & \quad \frac{\Gamma \vdash N \sim N'}{\Gamma \vdash \text{app} M N \sim (\text{app} M' N')}
\end{align*}
\]

**Context Schema** $S_r := is_{tm} x ; x \sim x$

The relevant substitution lemma is:

**Lemma 25.** If $\Phi_t, is_{tm} x ; x:A \vdash M : B$ and $\Phi_t \vdash N : A$, then $\Phi_t \vdash [N/x]M : B$. 
Proof. While this is usually proved by induction on the first derivation, we show it as a corollary of the substitution principles.

\( \Phi_r, \text{is_tm } x: A \vdash M : B \) by assumption
\( \Phi_r, \text{is_tm } N; N:A \vdash [N/x]M : B \) by parametric substitution
\( \Phi_r, \text{is_tm } N \vdash [N/x]M : B \) by hypothetical substitution
\( \Phi_r \vdash \text{is_tm } N \) by (implicit) assumption
\( \Phi_r \vdash [N/x]M : B \) by hypothetical substitution

We show only the R version of type preservation. For the G version, the context schema is obtained by combining the schemas \( S_r \) and \( S_t \) similarly to how \( S_{da} \) was defined to combine \( S_{xa} \) and \( S_{xd} \) in Sect. 3.3.1. We leave it to the reader to complete such a proof.

For the R version, we introduce the customary context relation, which in this case is:

\( \Phi_r, \text{is_tm } x : A \vdash \Phi_t, \text{is_tm } x : A \) by (implicit) assumption
\( \Phi_r \vdash \Phi_t \) by hypothetical substitution

Theorem 26 (Type Preservation for Parallel Reduction). Assume \( \Phi_r \sim \Phi_t \). If \( \Phi_r \vdash M \sim N \) and \( \Phi_r \vdash M : A \), then \( \Phi_t \vdash N : A \).

Proof. The proof is by induction on the derivation \( D : \Phi_r \vdash M \sim N \) and inversion on \( \Phi_r \vdash M : A \). We show only two cases:

Case:
\( D = x \sim x \in \Phi_r \)
\( \Phi_r \vdash x \sim x \) by rule \( pr_v \)

We know that in this case \( M = N \). Then the result follows trivially.

Case:
\( D_1 \)
\( \Phi_r, \text{is_tm } x : x \sim x \vdash M \sim M' \) by inversion on rule \( of_a \)
\( \Phi_t \vdash \text{app (lam x. M) N} \sim [N'/x]M' \) by inversion on rule \( of_t \)
\( \Phi_r \sim \Phi_t \) by assumption
\( \Phi_r, \text{is_tm } x : x \sim x \sim \Phi_t, \text{is_tm } x : x : A \) by rule \( crel_{rt} \)
\( \Phi_t \vdash [N'/x]M' : A \) by IH

If we were to prove a similar result for the polymorphic \( \lambda \)-calculus, we would need another substitution lemma, namely:

Lemma 27.
If \( \Phi_{ot}, \text{is_tp } \alpha \vdash M : B \) and \( \Phi_{ot} \vdash \text{isTp } A \), then \( \Phi_{ot} \vdash [A/\alpha]M : [A/\alpha]B \).
Again, this follows immediately from parametric and hypothetical substitution, whereas a direct inductive proof may not be completely trivial to mechanize.

4. Conclusions

We have presented an initial set of benchmarks that highlight a variety of different aspects of reasoning within a context of assumptions. We have also provided an infrastructure for formalizing these benchmarks in a variety of HOAS-based systems, and for facilitating their comparison. We have developed a framework for expressing contexts of assumptions as structured sequences, which provides additional structure to contexts via schemas and characterizes their basic properties.

As mentioned, in a related paper [Felty et al., 2015a], we compare four systems on the benchmarks presented here. We refer the reader to this paper for the details of the formalizations in Twelf, Beluga, Hybrid, and Abella, and for an extensive discussion of their comparison, along with a summary table comparing these systems on 13 features that we have identified. To give a flavour of this comparison, we mention two general points of comparison here. First, our results show that Beluga and Twelf are better suited to G versions of the theorems, while Abella and Hybrid are better suited to R versions. Furthermore, R versions are possible in Beluga, but not in Twelf, while G versions are possible to varying degrees in both Hybrid and Abella.

Another point of comparison is how much general support for HOAS (and beyond) that each system supports. In summary, Beluga provides intrinsic support for abstracting over variables and contexts, as well as for relating contexts via first-class substitutions and inductive definitions. Abella includes a special $\nabla$-quantifier to abstract over objects denoting variables and also provides inductive definitions. Contexts in both Abella and Hybrid must be handled explicitly. Hybrid lacks intrinsic support for abstracting over variables, which increases the burden on the user. While this is a significant drawback, Hybrid has several advantages. It inherits both inductive definitions and recursive functions from the ambient logic, which simplify proofs about context schemas and relations. In addition, it can directly take advantage of Coq’s tactics, libraries, and decision procedures.

This comparison has had the additional benefit of leading to or validating planned improvements to the systems. For example, Beluga now has better support for context relations, and there is continued work in this direction. One of the next steps for Hybrid is to implement the $\nabla$ quantifier, which will provide greatly increased support for context variables. There has also been new work in Abella in the direction of providing better support for automating lemmas about contexts.

Related work: Our approach to structuring contexts of assumptions takes its inspiration from Martin-Löf’s theory of judgments [Martin-Löf, 1996], especially in the way it has been realized in Edinburgh LF [Harper et al., 1993]. However, our formulation owes more to Beluga’s type theory, where contexts are first-class citizens, than to the notion of regular world in Twelf. The latter was introduced in [Schürmann, 2000], and used in [Schürmann and Pfenning, 2003] for the meta-theory of Twelf and in [Momigliano,
Benchmarks for Bindings

2000] for different purposes. It was further explicated in [Harper and Licata, 2007]’s review of Twelf’s methodology, but its treatment remained unsatisfactory since the notion of worlds is extra-logical. Recent work [Wang and Nadathur, 2013] on a logical rendering of Twelf’s totality checking has so far been limited to closed objects.

The creation and sharing of a library of benchmarks has proven to be very beneficial to the field it represents. The brightest example is TPTP [Sutcliffe, 2009], whose influence on the development, testing and evaluation of automated theorem provers cannot be underestimated. Clearly our ambitions are much more limited.

The success of TPTP has spurned other benchmark suites in related subjects, see for example SATLIB [Hoos and Stützle, 2000]; however, the only one concerned with induction is the Induction Challenge Problems (http://www.cs.nott.ac.uk/~lad/research/challenges), a collection of examples geared to the automation of inductive proof. The benchmarks are taken from arithmetic, puzzles, functional programming specifications, etc., and as such have little connection with our endeavor. A more recent version can be found in [Claessen et al., 2015]. On the other hand, Twelf’s wiki (http://twelf.org/wiki/Case_studies), Abella’s library (http://abella-prover.org/examples), Beluga’s distribution, and the Coq implementation of Hybrid (http://www.site.uottawa.ca/~afelty/HybridCoq/) contain a set of context-intensive examples, some of which coincide with the ones presented here.

Future Work Selecting a small set of benchmarks has an inherent element of arbitrariness. The reader may complain that there are many other features and issues not covered in Sect. 3. We agree and we mention some additional categories, which we could not discuss in the present paper for the sake of space.

— One of the weak spots of most current HOAS-based systems is the lack of libraries, built-in data-types and related decision procedures: for example, case studies involving calculi of explicit substitutions require a small corpus of arithmetic facts, that, albeit trivial, still need to be (re)proven, while they could be automatically discharged by decision procedures such as Coq’s omega. Thus, systems like Hybrid could take advantage of such procedures. At the same time, there are also specifications that are functional in nature, such as those that descend through the structure of a lambda term, say counting its depth, the number of bound occurrences of a given variable, etc.; most HOAS systems would encode those functions relationally, but this entails again the additional proof obligations of proving those relations total and deterministic. Case in point, the proof of correctness for the translation between De Bruijn and HOAS terms in Abella, see http://abella-prover.org/examples/lambda-calculus/debruijn_ho.thm, 40% of which consists of basic facts about natural numbers.

— In the benchmarks that we have presented all blocks are composed of atoms, but there are natural specifications, to wit the solution to the PoplMark challenge in [Pientka, 2007] or other case studies such as [Wang et al., 2013], where contexts have more structure, as they are induced by third-order specifications.

— Proofs by logical relations typically require, in order to define reducibility candidates, inductive definitions and strong function spaces, i.e., a function space that does not
only model binding. A direct encoding of those proofs is out of reach for systems such as Twelf, although indirect encodings exist [Schürmann and Sarnat, 2008]. Other systems, such as Beluga and Abella, are well capable of encoding such proofs, but differ in how this is accomplished, see [Cave and Pientka, 2015] and [Gacek et al., 2012].

Finally, a subject that is gaining importance is the encoding of infinite behavior, typically realized via some form of co-induction. Context-intensive case studies have been explored for example in [Momigliano, 2012].

One of the outcomes of our framework for expressing contexts of assumptions is the unified treatment of all weakening/strengthening/exchange re-arrangements, via the rm and perm operations. This opens the road to a lattice-theoretic view of declarations and contexts, where, roughly, $x \preceq y$ holds iff $x$ can be reached from $y$ by some rm operation: a generalized context will be the join of two contexts and context relations can be identified by navigating the lattice starting from the join of the to-be-related contexts. We plan to develop this view and use it to convert G proofs into R and vice versa, as a crucial step towards breaking the proof/type theory barrier. Another direction is abstracting over the structure of contexts, which is now tied up to sequences, possibly in the form of an abstract data-type of context construction that satisfies certain properties w.r.t. the rm and perm operations. This could help to capture more exotic context structures, such as the ones occurring in the logic of bunched implication.

Appendix A. Overview of Benchmarks

In this appendix, we provide a quick reference guide to some of the key elements of the benchmark problems discussed in Section 3. In the tables below, ULC (STLC) stands for the untyped (simply-typed) lambda-calculus, and POLY stands for the polymorphic lambda calculus. The entry “same” means that there is no difference between the R and G version of the theorem because there is only one context involved.

A.1. A Recap of Benchmark Theorems

<table>
<thead>
